

Asus shows off its next generation of mobile computing device concept at CeBIT 2011-- IRIS (Inspirational Research for Immersive Space)-- a device that turns into whatever its user needs it to be.

Using a form of paper thin flexible display, the device concept is stretchable; sliding the display's edges turns it from wristwatch size (attaching to a bracelet) to phone, tablet and gaming device.

The concept video also shows off a couple docks with built-in projectors, including an alarm-clock sized example that produces dynamic sleep environments (complete with ambient lighting and interactive 3D alarm projections).

Asus has a penchant for weird and wonderful hybrid creatures (like the Asus Eee Pad Slider), and the example shown at CeBIT actually works (sort of), but one seriously doubts the IRIS will get to exist someday. Then again, who knows what the future holds?
